PENEPMA Instructions (.geo files):

*additional information for these procedures is available on the PFE forum: <u>http://www.probesoftware.com/smf/index.php</u>

- 1. Open the **Standard.exe** (Standard) file with the following path: C:\Probe Software\Probe for EPMA
- 2. Choose the default **STANDARD.MDB** file
- 3. Check to see if there is a **secondary fluorescence (SF) problem** with the phases and corresponding elements of interest by running the Fanal. If you already know that an SF problem exists, skip to 4.
 - a. In the Standard.exe program, click the Analytical tab → PENEPMA (Secondary Fluorescence Profile) Calculations

- b. To run the program, you will have to **create .PAR and .MAT files** for your phases. You do this on the left side of the screen.
 - i. **.PAR files** take ~10 hours to run, so **make sure adequate files don't already exist in the penfluor folder** with the following path: C:\UserData\penepma12\penfluor
 - ii. Here are **links on the PFE forum** for PAR files as they are **updated periodically:**

http://probesoftware.com/smf/index.php?topic=13.msg23#msg23 http://probesoftware.com/smf/index.php?topic=119.msg1638#msg1638

-Primary Intensity Calculations (create .PAR files for one or all .MAT files) (~10 hours each at 3600 sec)										
	Create Material Files in PENEPMA		Bun Penfluor and Fitall for							
Mat. A	Cu.mat	Browse	ALL three materials							
Mat. B	Co.mat		Browse	generate .PAR files						
Mat. B Std	Co.mat		Browse	Run Penfluor/Fitall for Material A Only						
	Time (in seconds per simulation, x10)	3600		Run Penfluor/Fitall for Material B Only						
	Number of Simulations (in electrons, x10)	2.0e+09		Run Penfluor/Fitall for Material B Std Only						

- iii. .MAT files can be created using the lists provided or by entering in a formula
 - 1. Make sure the **density is accurate** for your .MAT files. Before typing in the formula for the phase, make sure you have entered the correct density.

iv. You will need to create **.PAR and .MAT files** for **the phases of interest and the standards** you will use on the probe for elements likely affected by SF (e.g., ~1 micron spherical inclusions of Fe,Ni-metal in pyrrhotite grains)

- 1. Material A = incident beam phase (e.g., Fe,Ni-metal)
- 2. Material B = boundary phase (e.g., pyrrhotite)
- 3. Material B std = primary standard (e.g., pyrite for S, Fe metal for Fe, Ni metal for Ni)
- c. After the .PAR and .MAT files have been created, you can **run the program** to determine if SF is an issue for your materials. You do this on the right side of the screen.

Element Co 🗸 X-Ray ka	Microns 50 Points 50	Copy To Clipboard
Run Fanal (generate k-ratio file for couple boundary)	☐ Send To Excel ✓ Use Grid Lines ☐ Use Log Scale Zoom Full	.000000

- i. Enter in all the required information making sure **Material B std includes the element** you are running the program for
- ii. Click "Run Fanal (generate k-ratio file for couple boundary)" button
- iii. You can extract the resulting plot by clicking the "**copy to clipboard**" button and pasting it into an appropriate program like MS paint, Adobe photoshop, or MS powerpoint
- iv. If any of your elements show a SF issue near the boundary between the two phases of interest, proceed. Otherwise, no additional corrections to microprobe data are required
- 4. Since SF is a problem with at least one element your analyzing for, you will need to **generate corrections for this effect**
 - a. In the Standard.exe program, click the Analytical tab → PENEPMA (Monte Carlo) Calculations

Welcome to Standard, Probe for EPMA (Xtreme Edition) v. 10.3.6 Copyright (c) 1995-2014 John J. Donovan								
This software is registered to : Sheri Singerling UNM8200								
Press the F1 key in any window for context sensitive help. To get help on a menu item simply highlight with the mouse and hit the F1 key.								

b. To generate corrections, you have to **create .IN files** for your incident beam phase with the boundary phase and any standards. This program also takes into account the **geometry of your phases**.

- i. You will likely want to **decrease the simulation time** as the default is ~27 hours. Go with whatever will give to low uncertainities (I usually do 3600 s).
- ii. Choose the **"Optimize Secondary Fluorescent X-rays (use couple or sphere *.geo files)"** option
- iii. Load your .MAT files for the beam incident phase and adjacent phase using the browse buttons
 - 1. You want to make sure to **avoid using the Taylor series premade** .**MAT files**. These do not seem to work when you try to make .IN files for them.
- iv. Load the correct geometry file using the browse button (1mic_sphere.geo). Note that this file must have the following path: C:\Probe Software\Probe for EPMA\penepma12\Penepma. There are many geometry files in the penepma12 folder, but you have to move the one you want into the Penpma folder within. *Changing this will change the beam position's x value to a non-zero value. Make sure to change it back to 0.*
- v. Make sure that the "minimum electron/photon energy" boxes include the x-ray lines you are measuring for. Sometimes the values in these boxes change when you are inputting all your parameters and may exclude the x-ray lines you are interested in. Keeping it at the default value of 1.0e3 is a safe bet.
- vi. Name your .IN file and click "Create PENEPMA Input File".
 - 1. You must **do this for the incident beam phase which includes the boundary phase and any standards used for the elements** of interest.
 - 2. For the **standard** .IN files:
 - a. Choose the **"Optimize Production of Characteristic X**rays" option
 - b. Use the **bulk geometry file**
 - c. Since PENEPMA does not distinguish the intensity produced from SF and the intensity produced from the actual sample, you will need to run a **bulk geometry for your incident phase** as well
 - i. In an example where both the inclusion and the surrounding phase have a given element, like Fe in Fe,Ni-metal and FeS, the emitted intensity for Fe can be both characteristic x-rays or secondary fluoresced x-rays. This bulk run will allow you to tease apart the two intensities.
- **c.** After you have created all your .IN files, you are ready to **run the program for k ratio corrections**
 - i. Still in the same window, click the "Batch Mode" button on the far right
 - ii. In the new window that pops up, highlight all .IN files you will use

- PENEPMA Batch M	PENEP ode Processin	MA- Batch M g	ode	
Copper metal.in Fe90Ni10.in FeS.in metal.in	11/2 5/27/ 5/27/20	0/2011 11:40:1 /2014 2:17:57 F 014 2:21:16 PM 014 2:20:58 PM	4 AM *M	Close Select the input files to run from the PENEPMA12 folder, then select a project folder for the output results to be stored in, then click the "Run Batch" button. Results from each input file will be stored in a separate folder in the specified project folder.

```

5. To **correct your concentrations** (in wt.%) from microprobe data, you will need to convert the SF **intensities into wt.%** for each element which involves several steps. Here is an abbreviated version:

a. $I_A^{geometry} - I_A^{bulk} = I_A^{unknown}$

- b. (CA^{std}/[ZAF]A^{std}) x (IA^{unknown} / IA^{standard}) = K ratioA
- c. K ratio_A x 100 = K ratio_A % and (K ratio_A %) x ([ZAF]_A^{unknown}) = C_A^{unknown}
 - a. Tease apart the SF contribution to intensity from the total intensity
 - i. This is why you ran a "bulk" geometry file for your incident beam phase in 4.v.b
 - ii. Simply subtract the intensity of your incident beam phase from the bulk geometry (i.e., Fe90Ni10 with bulk.geo) from your incident beam phase with the correct geometry (i.e., Fe90Ni10 with 1mic_sphere.geo) $I_A^{geometry} - I_A^{bulk} = I_A^{unknown}$ (where A is your element)
 - b. Generate the **k-ratio**
 - i. If you used a pure element standard, simply divide the intensity from a. by the intensity from your standard (which is from the in-tens-01.dat file for your standard)

K ratio = $I_A^{unknown} / I_A^{standard}$ (where A is your element)

- ii. If you **did not use a pure element standard**, you must take into account that your **k-factor does not equal 1**.
 - 1. **K factor** = $C_A^{std}/[ZAF]_A^{std}$ (where C is the fraction of your standard that is the element A and [ZAF] is the ZAF correction for element A for the standard). In pure element standards, both of these terms equal 1.
 - 2. **Determine** C by simply looking at the formula for your standard. For example if you used pyrite FeS_2 as your standard for S, C for sulfur is 2/3.
 - 3. Determine [ZAF] by using CALCZAF.

a. Open the **Calczaf.exe** (with the following path: C:\Probe Software\Probe for EPMA)

lement	Analyzed	Cations	Stand	lard	Std K-fac.	Std Inten.	Unk Wt.	%	Unk K-	fac.	
Enter (Composition a	s Formula Strin	ig a	Ехс	el Options	Calcula	<mark>te</mark> Cal	culat) ptior	ion 1s	Clos	se
Enter Enter	Composition f	From Database	Concer	> Intration	>Excel Help S	Load N	se All Matrix I ext Datas r	Corre et Fre	otions om Inpu	ut File	;

b. You can either **enter the elements manually or type in the mineral formula** for your non-pure element standard.

- c. Click the "Calculate" button
- d. The output screen displays the [ZAF] for each element under the "ZAFCOR" column

File Edit	Standard	Xray Analy	tical Run/	Output	Help

CHOICE PROPERTY AND											~

4. Now simply **divide C by [ZAF]** to get the K-factor.

5. Multiply your K-factor by the intensity of the unknown over the intensity of the standard

K ratio_A = $(C_A^{std}/[ZAF]_A^{std}) \times (I_A^{unknown} / I_A^{standard})$

- c. Convert the **k ratio into concentration**
 - i. You must have the k ratio in wt.% to apply the correction to your microprobe data.
 - ii. To convert from k ratio to wt.%:
 - 1. Turn the k ratio into k ratio % by multiplying it by 100 K ratio_A x 100 = K ratio_A %
 - 2. Turn k ratio % into wt.% by multiplying it by $[ZAF]_A^{unknown}$
 - a. Again, use CALZAF to determine [ZAF] for the element of interest or even use the actual ZAF corrections provided in the output of your microprobe data (excel spreadsheet)

(K ratio_A %) x ($[ZAF]_A^{unknown}$) = $C_A^{unknown}$

d. You now have the **concentration of the element of interest (in wt.%) due to SF**. To correct your microprobe data, simply subtract this concentration to your microprobe data.

CA^{unknown}_microprobe - CA^{unknown}_SF
